Drivers of metapopulation dynamics

Area, isolation assumed to serve
as surrogates for habitat quality

Speyeria nokomis apacheana

Arid, montane landscape

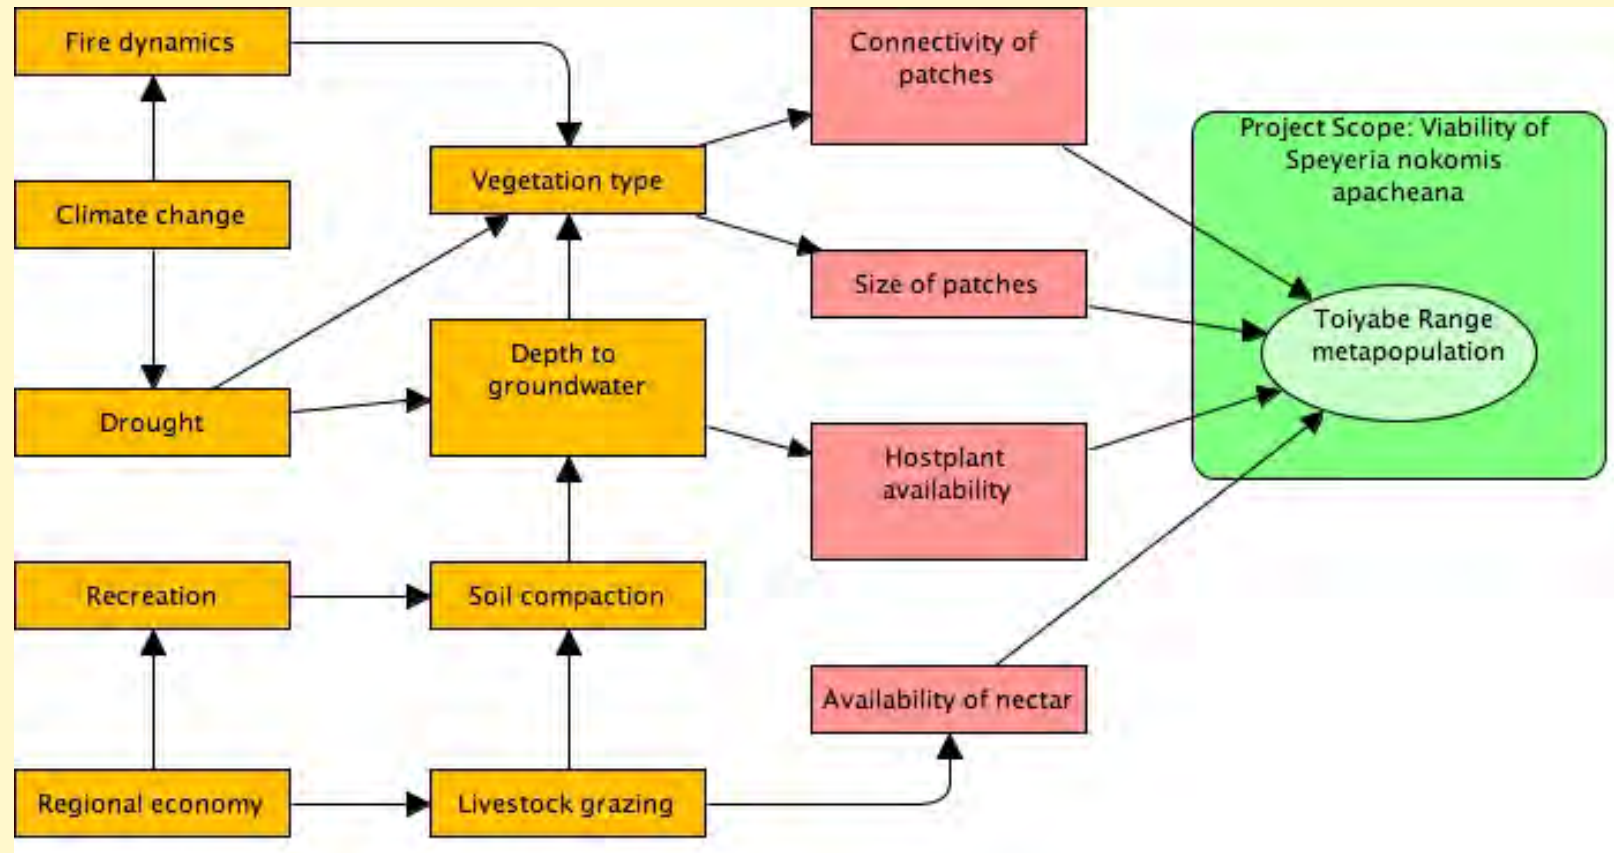

Isolated patches of habitat

Mark-recapture data

Patch geometry, vegetation

Direct drivers

Management interventions

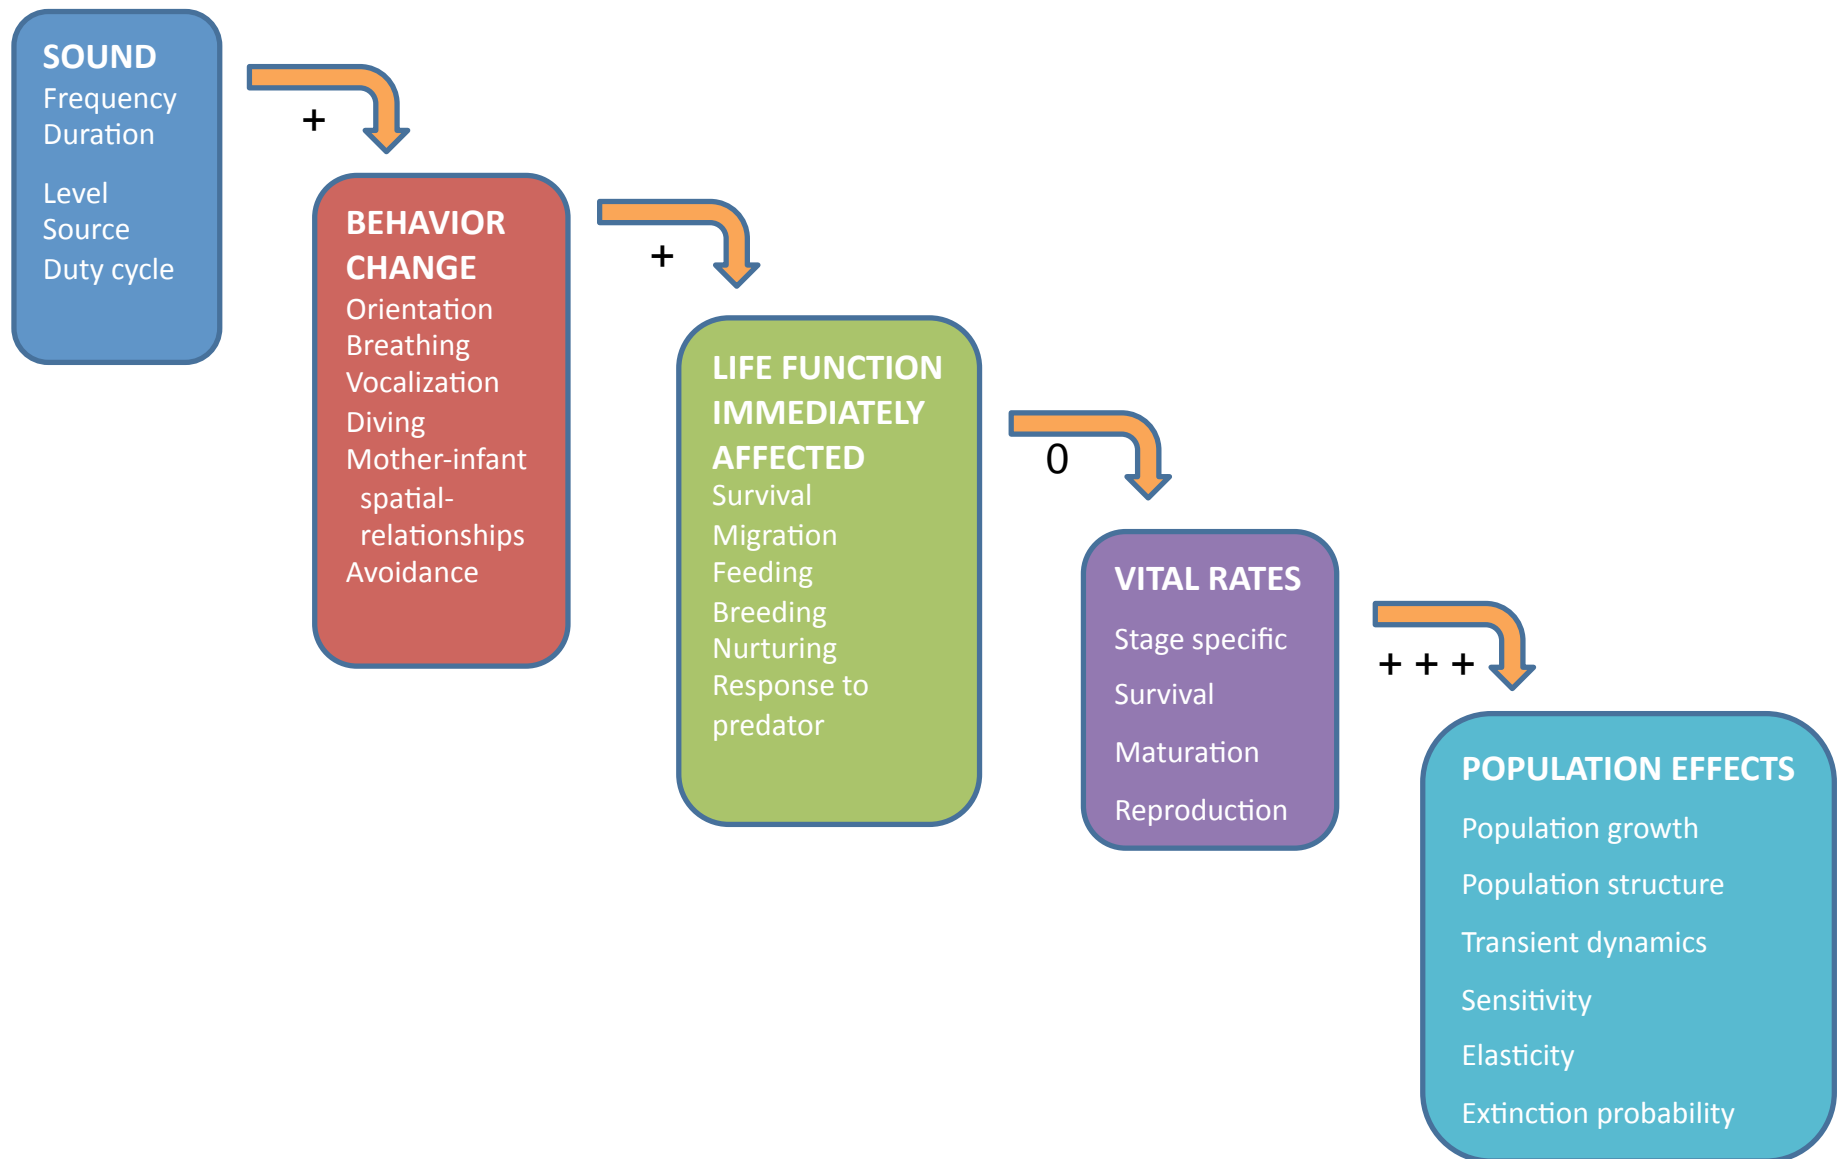

- Delay grazing in wet meadows
- Minimize summer camping
- Restrict herbicide use in riparian areas

Population-level effects of disturbance on marine mammals

- No universally applicable algorithm for estimating population-level effects
- Types and strength of inference given different organisms, data types, quantitative methods

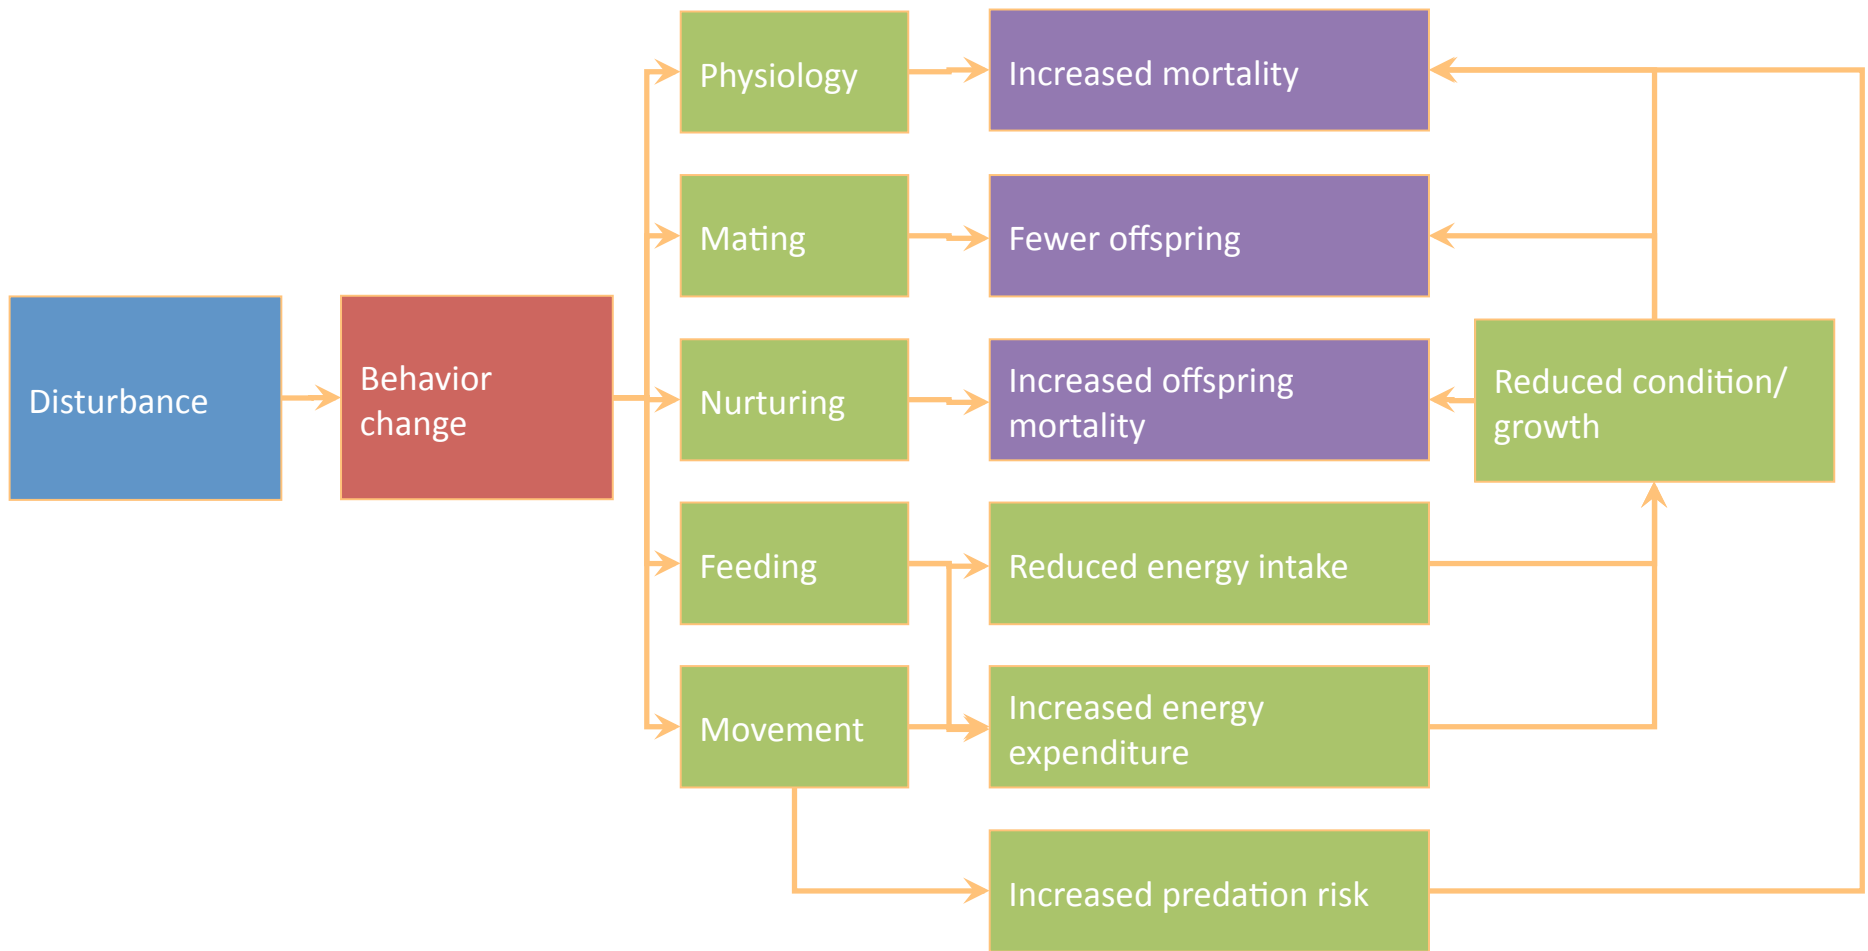

Objective

Guidance for identifying, quantitatively estimating mechanisms by which population dynamics may respond to changes in baseline behavior of individuals

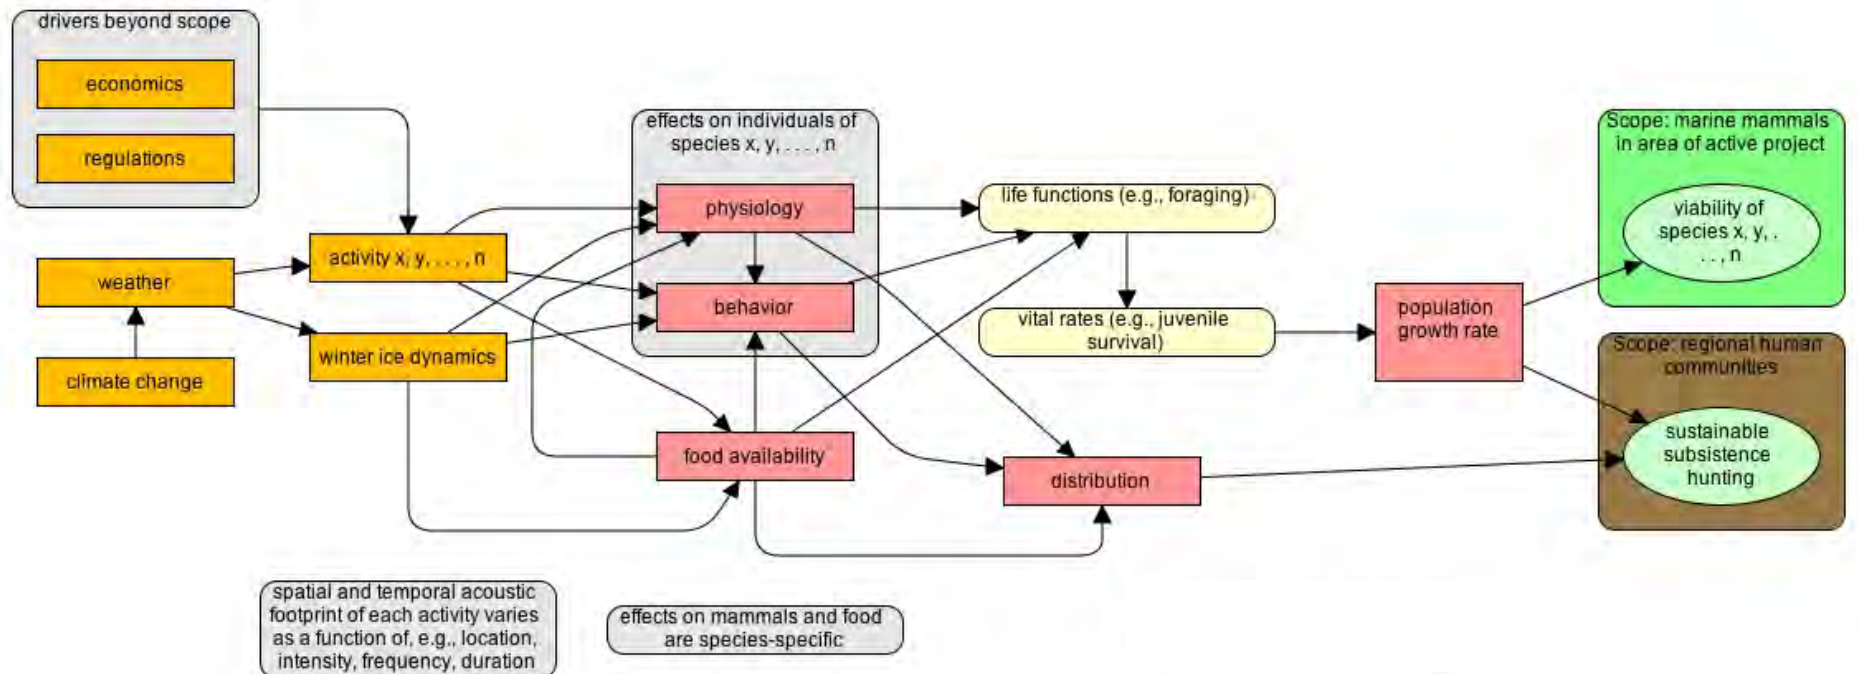

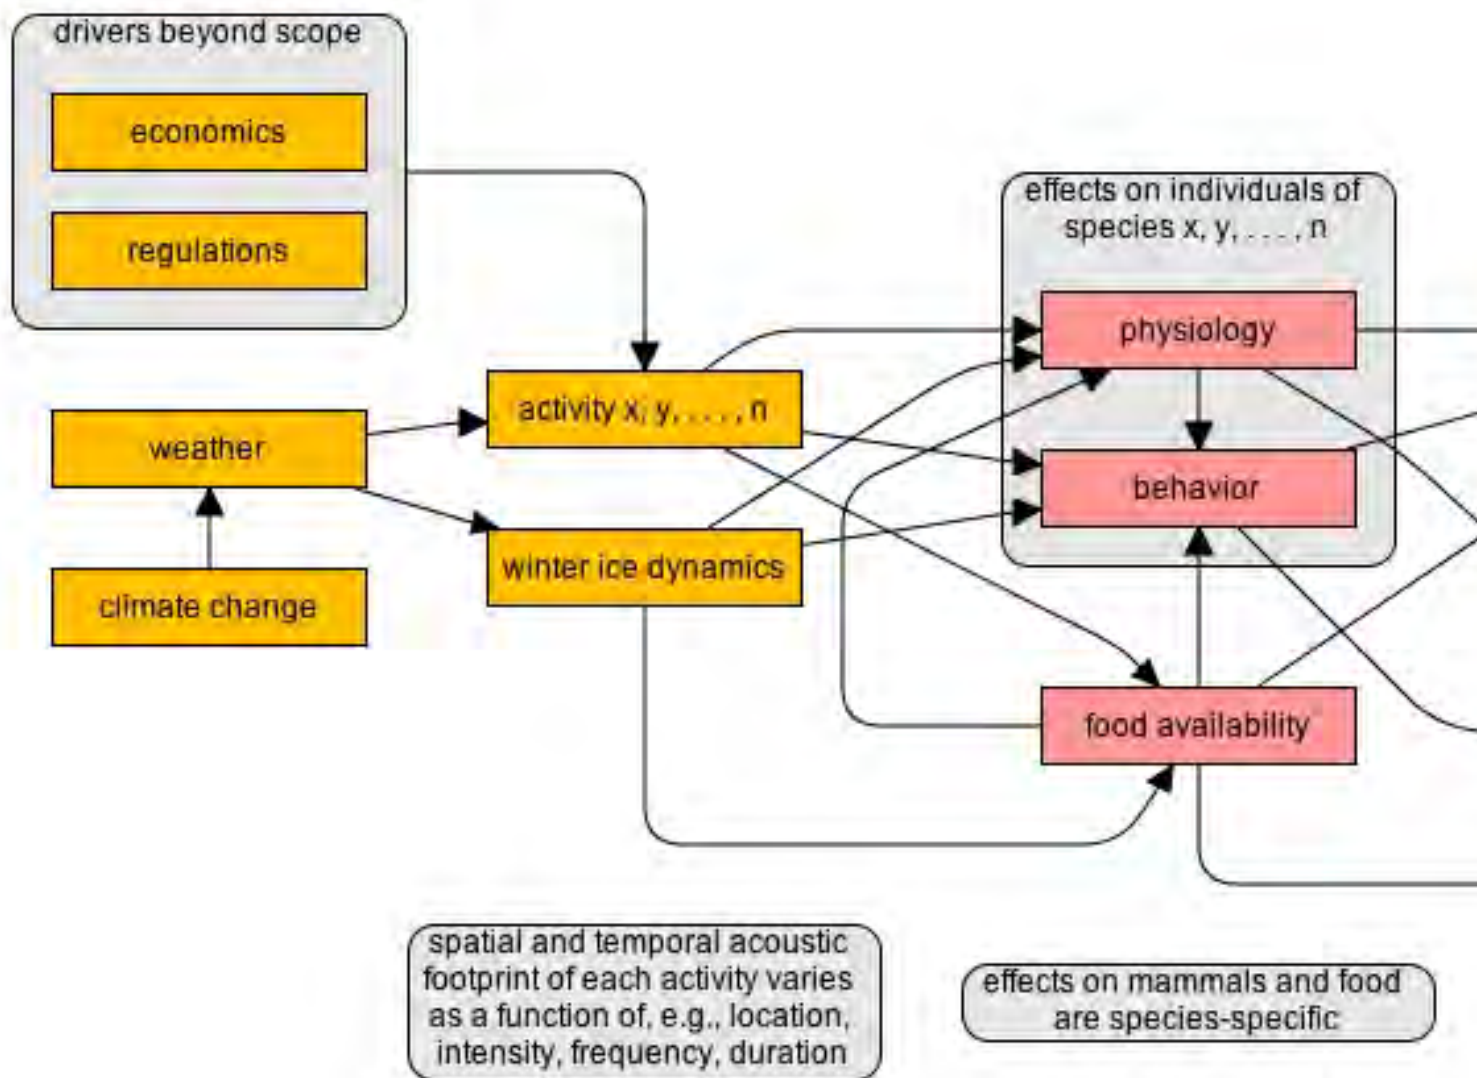

Illustrative steps

- Identify high-priority functional groups
- For each group, identify life functions known or assumed to have greatest effects on vital rates
- Identify measures of those life functions and methods of measurement
- Hypothesize how life functions respond to changes in behavior, highlight uncertainties
- Identify methods to test those hypotheses

Outcomes

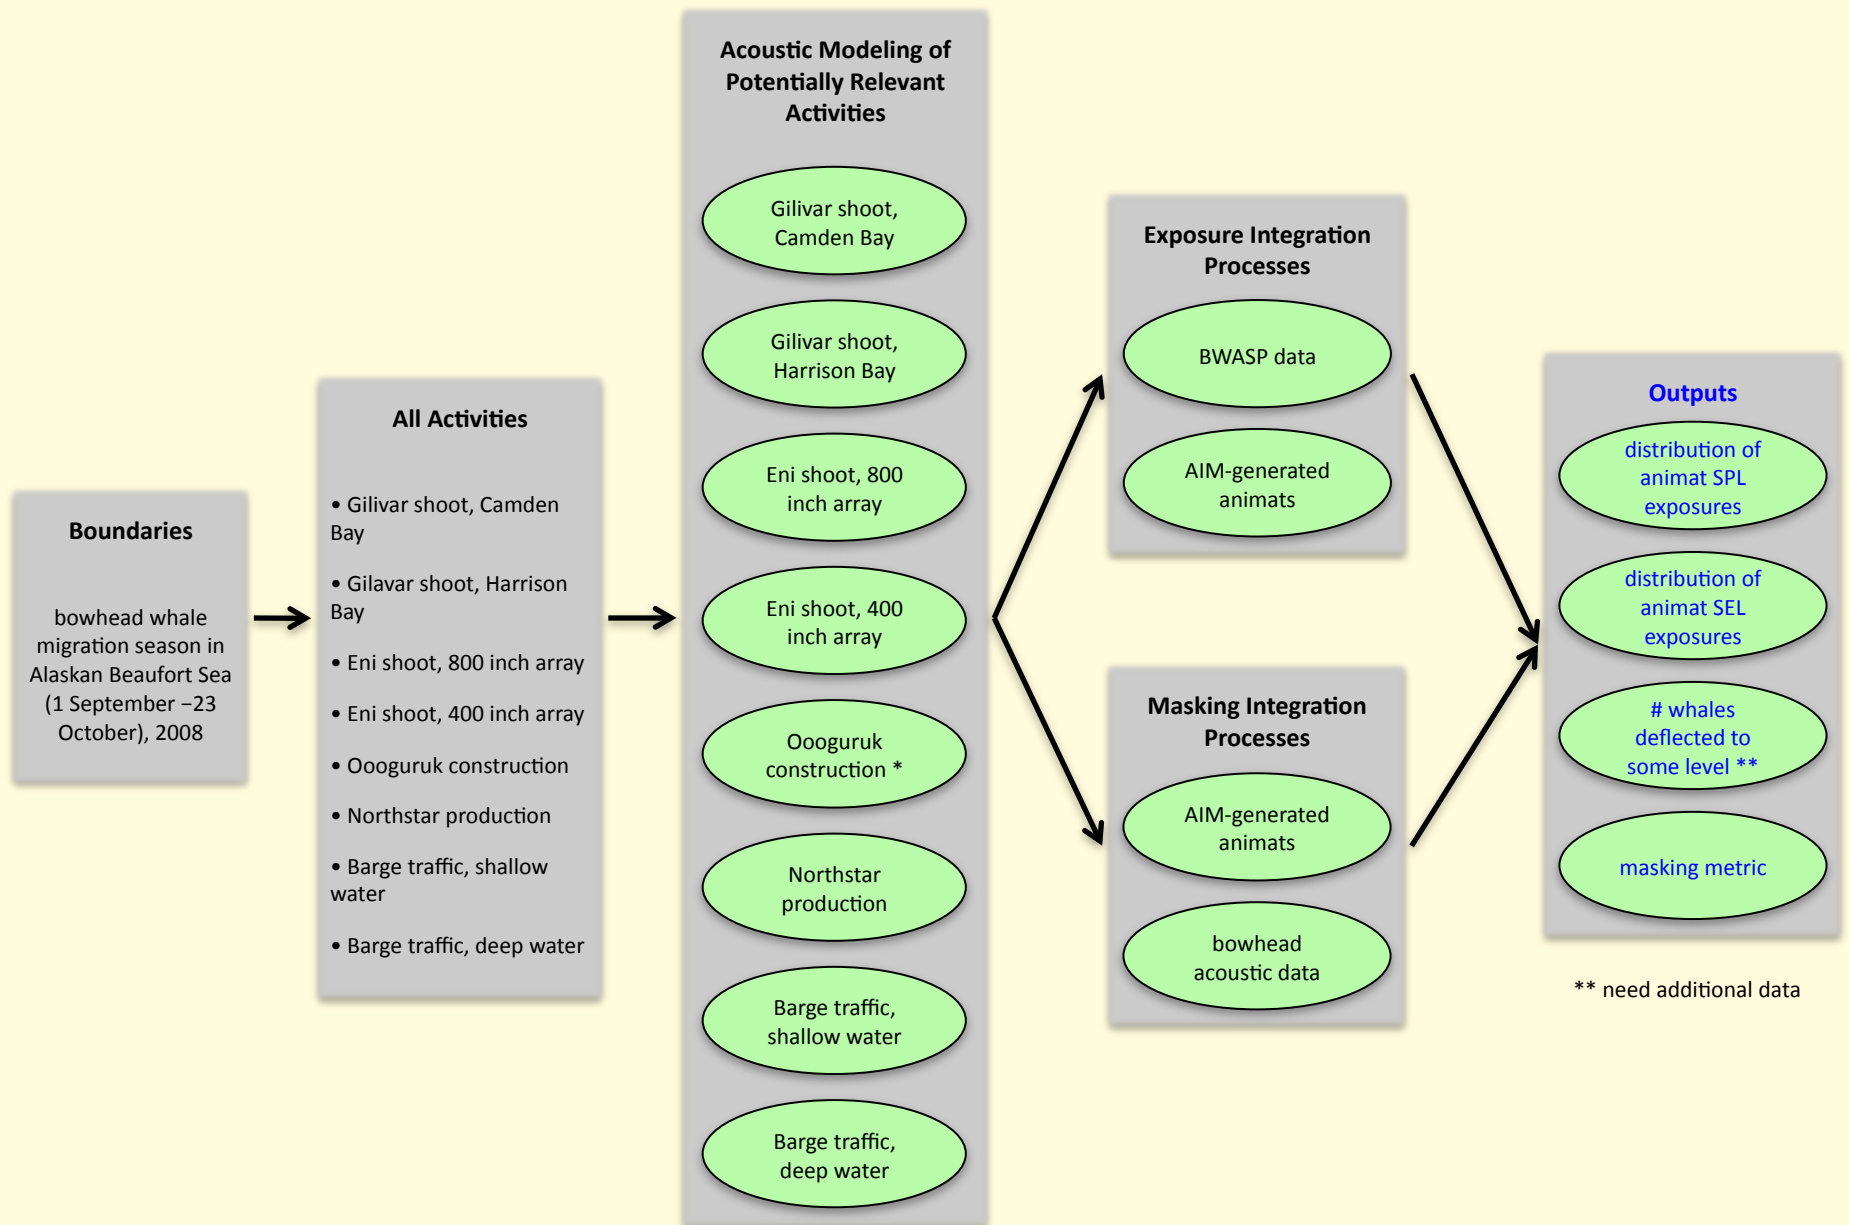

- Classify taxonomic groups along gradient of feasibility of estimating individual and population-level effects of disturbance
- Identify needs for empirical data, quantitative or qualitative methods, technological advances
- Prioritize data collection, technology development, modeling in an objective, repeatable manner

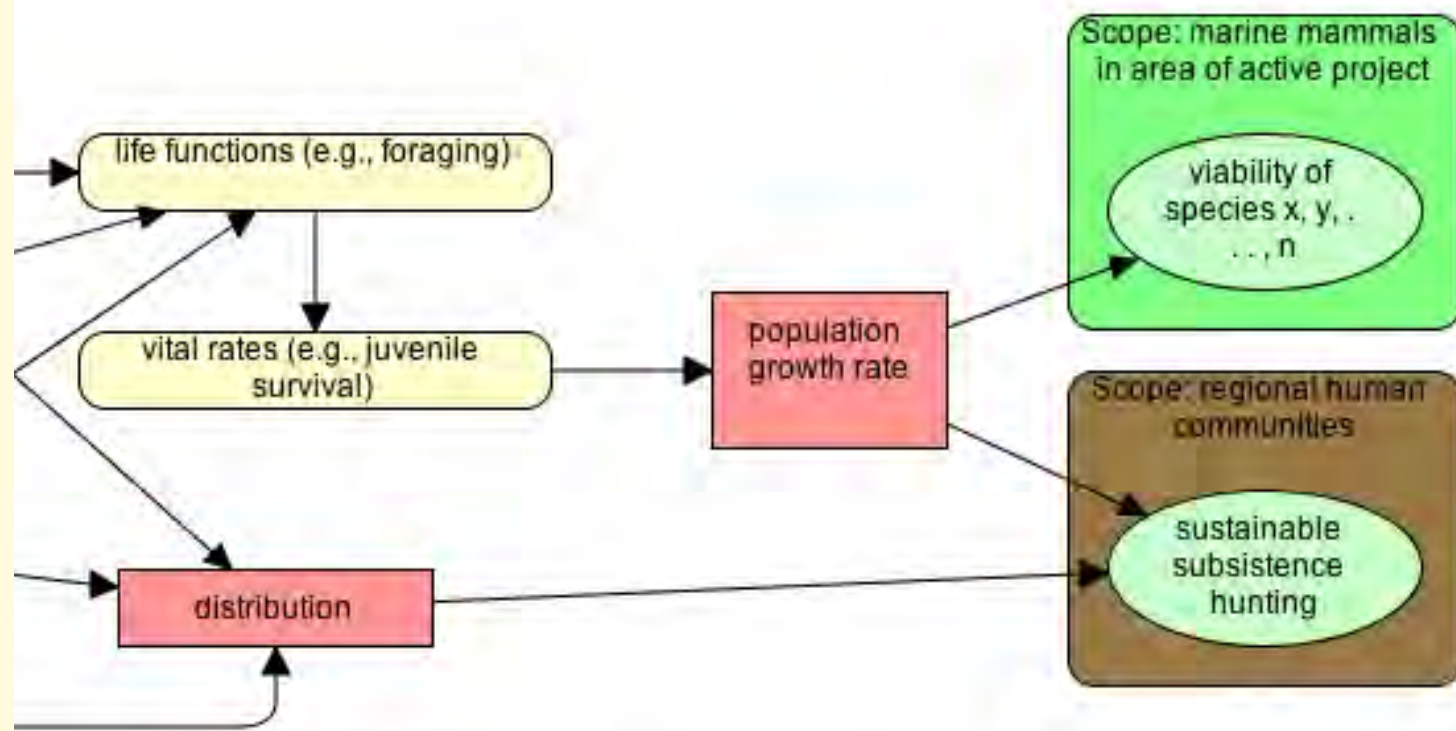

Cumulative effects of underwater sound

* hypothesis: footprint will be small, will drop out

** need additional data

Scenario 1: expansion
of pinyon-juniper
woodlands by 2100

Scenario 2: contract
extent of riparian
cover by 10%

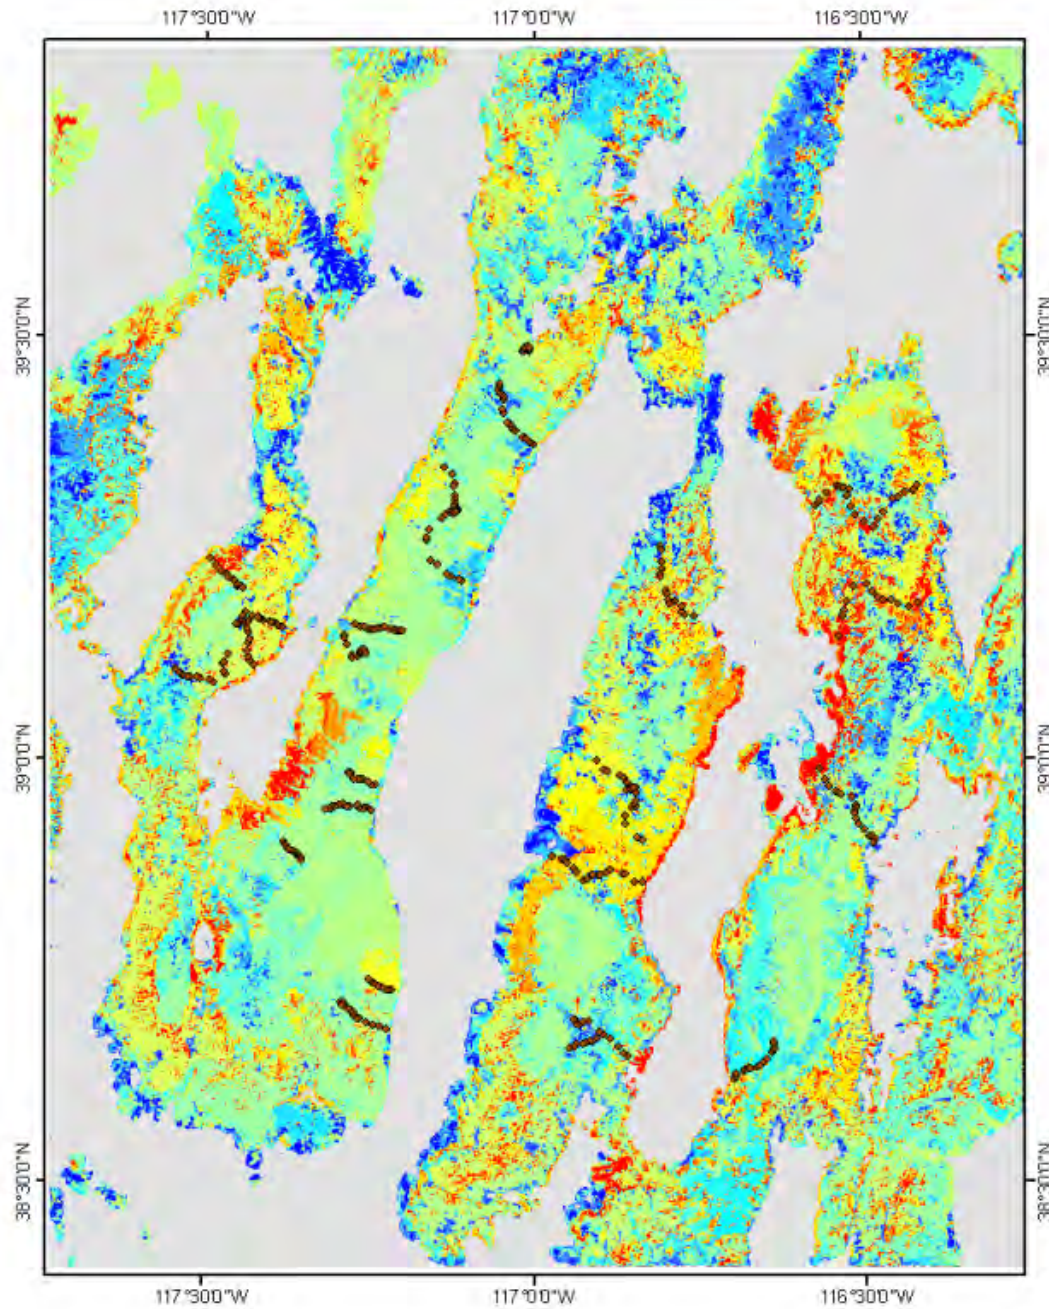

Color intensity
proportional to
percent cover lost

Structural
connectivity: static
features of habitat
that are associated
with occupancy

Future probabilities
of occurrence if
pinyon-juniper
woodlands expand
as projected

Changes in probabilities of occurrence (blue = increase, red = decrease)

Can intervention influence the outcome?
